

10 The diagram shows a protein molecule.

Two long polypeptides each form α -helices for much of their length and these twist together into a fibre.

At one end, each of these polypeptides coils into a globular head.

Two short polypeptides bind to each globular head.

What describes the protein structure of this molecule?

- A quaternary structure because each molecule consists of six polypeptides
- B secondary structure because the long polypeptides form α -helices
- C tertiary structure because the α -helices form a fibre
- D tertiary structure because the heads form globular proteins
