

40 Tetanus is a bacterial infection.

The graph shows the blood antibody concentration of two people.

On day 0, person G was injected with antibodies to the tetanus toxin and person H was injected with the vaccine for tetanus.

What could be the result if G and H were infected with the tetanus bacteria on day 20?

- A** Tetanus antibodies would not be produced in person G.
- B** Antibody production would peak after day 32 in person G.
- C** Antibody concentration would stay constant in person H.
- D** A second antibody peak would occur in person H that would be lower than the first peak.
