

- 32** What explains how the maximum uptake of oxygen occurs as blood passes through the capillaries of the lungs?
- A** Each haemoglobin molecule can temporarily bind to four oxygen atoms.
 - B** Oxyhaemoglobin formation increases the capacity of red blood cells to transport oxygen.
 - C** The binding of the first oxygen molecule to haemoglobin decreases the molecule's affinity for binding other oxygen molecules.
 - D** The dissociation of carbon dioxide from carboxyhaemoglobin allows more haemoglobin to be available for oxygen binding.
