

Question	Marking guidance	Mark	Comments
07.1	(Anti-AQP4) antibody has a (specific) tertiary structure; - Has binding site / variable region that only binds to / complementary to one <u>antigen</u>; - Antigen to this antibody (only) found on these nerve cells; - So, antibody (only) binds to / forms antigen-antibody complex with these nerve cells (causing damage);	4	Reject “active site” (only penalise once if it occurs throughout) 3. / 4. Accept ‘receptor’ for antigen
07.2	- Only 20 in the study; OR Only one study; - For some concentrations of antibody there is a range in the number of vertebrae surrounding damaged nerve cells; - No statistical test used; - Correlation is weak;	3 max	- Accept small sample - Accept suitable use of data - Accept converse
07.3	- The monoclonal antibody binds to nerve cell antigen so less / no anti-AQP4 can bind; OR The monoclonal antibody forms antigen-antibody complex with nerve cell antigen so less / no anti-AQP4 can bind; - When monoclonal antibody binds it doesn’t cause damage to nerve cell;	2 max	It = monoclonal antibody 1. Reject “active site” Ignore “competitive inhibitor” Accept receptor for antigen Do not credit responses in the context of enzymes
