

- 24** The diagram shows the structures of some drugs that have a similar structure to nucleotides. The presence of these drugs reduces nucleic acid synthesis.

acyclovir

gancyclovir

Which statement explains how these drugs reduce nucleic acid synthesis?

- A** They prevent peptide bonds forming between amino acids.
- B** They are non-competitive inhibitors of the enzymes that catalyse the synthesis of DNA or RNA.
- C** They bind to pyrimidine nucleotides and the base pair is the wrong size.
- D** They replace purine nucleotides, causing the synthesis of incomplete nucleic acids.
