

Question	Marking Guidance	Mark	Comments
07.1	1. (Dopamine) <u>diffuses</u> across (synapse); 2. Attaches to <u>receptors</u> on <u>postsynaptic membrane</u> ; 3. Stimulates entry of sodium <u>ions</u> and depolarisation/action potential;	3	2. Ignore name/nature of receptor e.g. cholinergic 3. Accept Na ⁺ for sodium ions 3. Accept generator potential for action potential
07.2	1. Morphine attaches to <u>opioid</u> receptors; 2. (More) dopamine released (to provide pain relief);	2	1. Reject reference to active site 2. Reject receptors release dopamine
07.3	1. (Inside of postsynaptic) neurone becomes more negative/hyperpolarisation/inhibitory postsynaptic potential; 2. More sodium ions required (to reach threshold) OR Not enough sodium ions enter (to reach threshold); 3. For depolarisation/action potential;	3	1. Ignore K ⁺ 1. Accept -75mV or any value below this as equivalent to more negative 1. Accept 'decrease in charge' 2. Accept Na ⁺ for sodium ions 3. Context must convey idea that depolarisation / action potential is less likely
